# Measurement of Normalized Differential Top-Quark Pair Production Cross Sections

Ivan Asin on behalf of the CMS Collaboration
LHCC Poster Session, 2013/03/13 Geneva (Switzerland)

Introduction & Motivation

Within the Standard Model (SM) the top quark plays an important role:
- same $t\bar{t}$ and Higgs boson production process at the LHC energy regime (gg fusion)
- t-quark physics important test of SM

The LHC 2012 data taking period:
- produced a large number of $t\bar{t}$ events, ~5M
- **allows precision measurements of SM**
- in a new energy regime $\sqrt{s}$ = 8 TeV

The measurement of normalized differential cross section is performed in the l+jets and dilepton decay channels of the $t\bar{t}$ pairs.

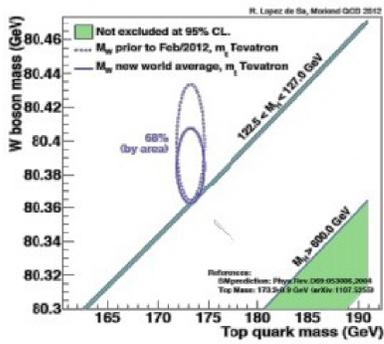

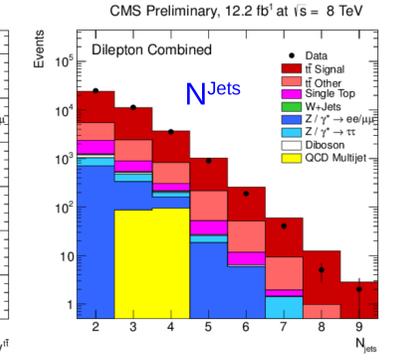

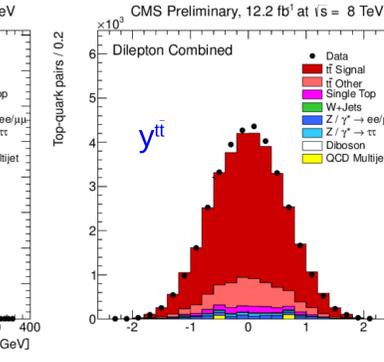

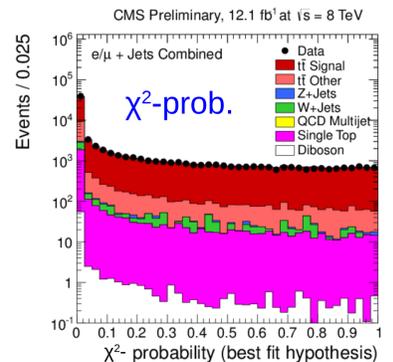

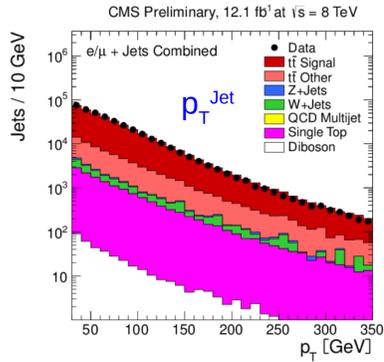

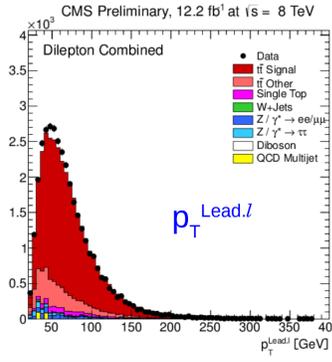

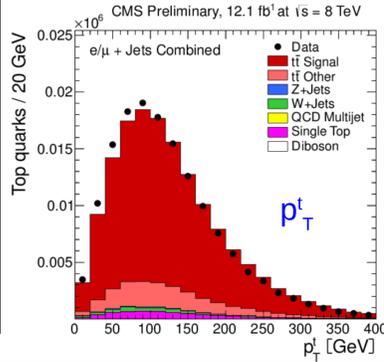

Event Selection & Reconstruction

Dilepton
At least 2 isolated leptons (e or μ)
- opposite sign
- p_T >20 GeV/c and $|\eta|$ < 2.4
- m_{ll} > 20 GeV/c²

At least 2 jets
- p_T >30 GeV/c and $|\eta|$ < 2.4

At least 1 b-tag jet

Only in ee or $\mu\mu$ channels
- $| m_{ll} - m_Z |$ > 15 GeV/c²
- E_T^{Miss} > 40 GeV/c

l+jets
1 isolated leptons (e or μ)
- p_T >30 GeV/c
- $|\eta|$ < 2.1
- veto additional leptons

At least 4 jets
- p_T >30 GeV/c
- $|\eta|$ < 2.4

At least 2 b-tag jets

Unfolding & Normalized Differential Cross Sections

Why:
- correct the measurement for experimental migrations
- due to the finite resolution of the measurement

Method:
- regularized unfolding
- to **minimize** the global bin-by-bin **correlations**

Binning selection:
- keep migrations into the bins (purity, p^i) is above 40-50% in each bin

$$\frac{1}{\sigma}\frac{d\sigma}{dX} = \frac{1}{\sigma}\frac{N_{data}^i - N_{bg}^i}{\Delta X^i \epsilon^i L}$$

$$p^i = \frac{N_{rec\&gen}^i}{N_{rec}^i} \qquad s^i = \frac{N_{rec\&gen}^i}{N_{gen}^i}$$

Normalized differential cross sections measured in:
- full phase space: t-quark and $t\bar{t}$ pair properties
- visible phase space: lepton and/or jet properties

Visible Phase Space

Dilepton
Leptons
- p_T > 20 GeV
- $|\eta|$ < 2.4

b-jets
- p_T > 30 GeV
- $|\eta|$ < 2.4

l+jets
Leptons
- p_T > 30 GeV
- $|\eta|$ < 2.1

Jets
- p_T > 30 GeV
- $|\eta|$ < 2.4

$t\bar{t}$ Event Reconstruction

$t\bar{t}$ system directly not measurable → event reconstruction
Input objects: reconstructed l, jets and E_T^{Miss}

Dilepton
- system underconstrained due to 2 ν's
- $E_T^{Miss} = p_T(\nu) + p_T(\bar{\nu})$
- m_W = 80.4 GeV
- $m_t = m_{\bar{t}}$ = fixed
- m_t varied in 1 GeV steps in [100, 300] GeV range
- prefer solutions with b-tagged jets
- then with most probable ν spectrum

l+jets
- vary l, jet and ν 4-momenta
- $E_T^{Miss} = p_T(\nu)$
- m_W = 80.4 GeV
- $m_t = m (qq'b) = m(l\nu b)$
- consider only the 5 leading jets
- b-tagging information used for b-jet association
- choose jet permutation that maximizes χ²-probability

Results

First CMS differential cross section measurements at $\sqrt{s}$ = 8 TeV are shown as function of transverse momentum, (pseudo-)rapidity and invariant mass of the final state lepton, lepton-pair, b-jet, top quark and top-quark-pair system.

Bin-center-correction applied to the measured data points. For comparison with respect the measurement MadGraph, POWHEG, MC@NLO and Approx. NNLO (when available) predictions shown.

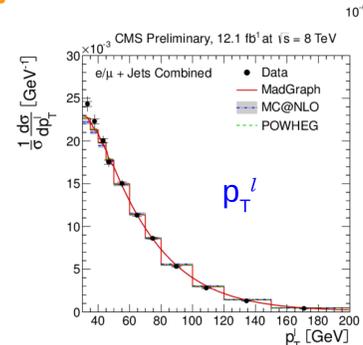

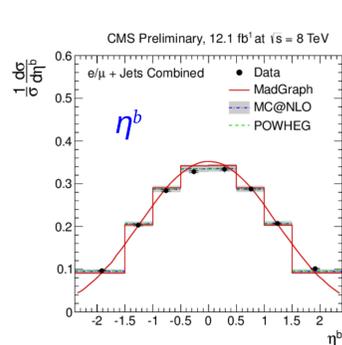

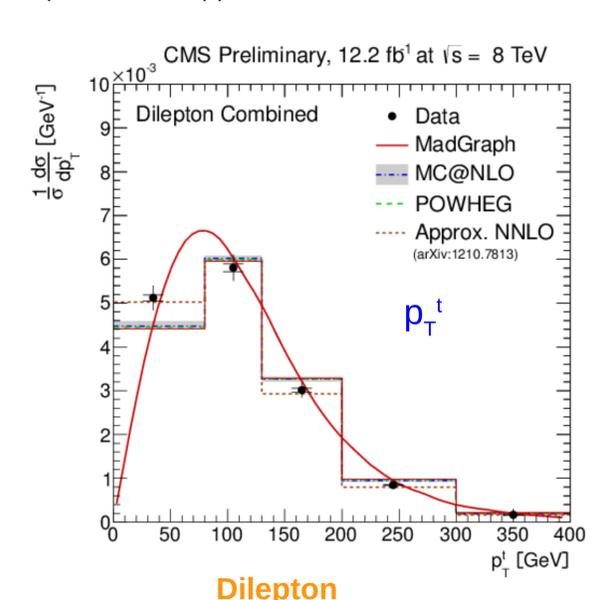

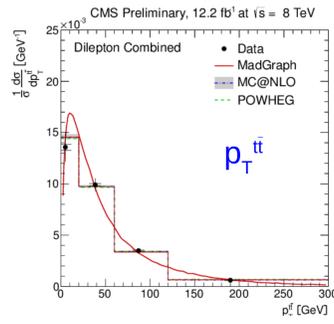

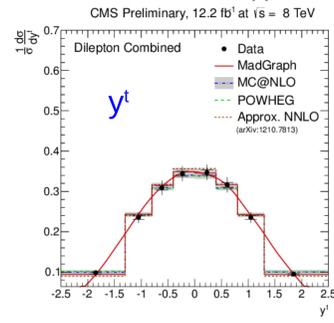

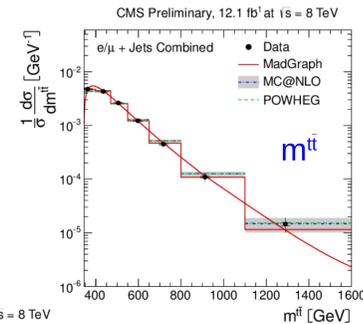

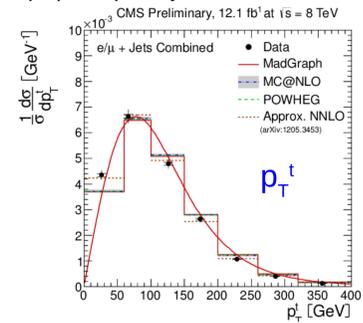

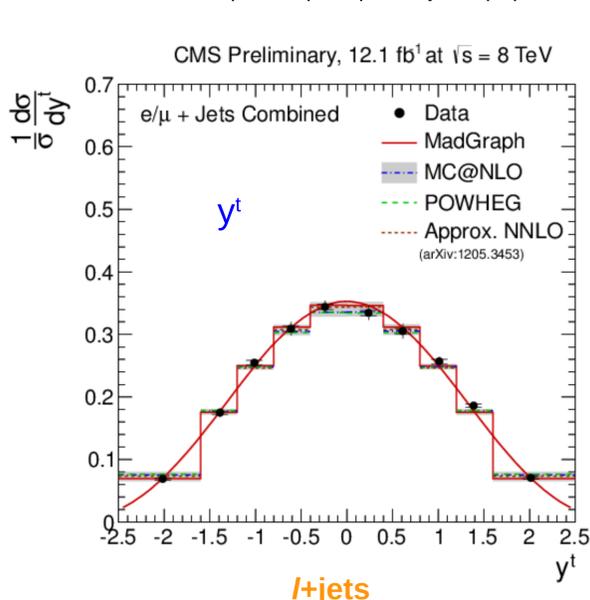

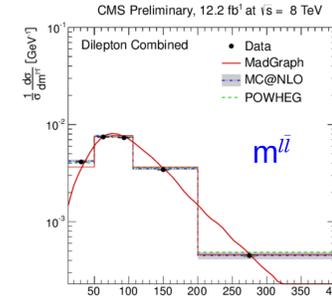

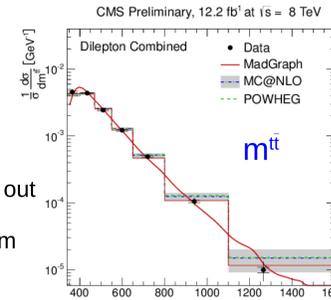

Summary

$t\bar{t}$ differential cross sections in l+jets and dilepton channel are measured. Results show a **good agreement with SM** predictions within the uncertainties, although top quark transverse momentum prefers Approx. NNLO predictions.

Uncertainties

Estimated independently in each
- bin
- distribution
- channel

Global uncertainties cancel out
- due to normalization

Main uncertainties arise from
- Q^2 scale: 1-4%
- Matching: 1-3%
